Could You Have Thinning Bones or Osteoporosis?

Osteoporosis is a disease in which bones become thin and weak causing them to break more easily. It is often called a “silent disease” because there are no symptoms; you can’t feel your bones becoming weak.

You may be at risk if you...

• Are over 50 years old
• Are postmenopausal
• Have low body weight (<125 lbs.)
• Smoke
• Had a past fracture of the hip, spine, or wrist (especially since menopause)
• Have a family history of osteoporosis or hip, spine, or wrist fracture (in a post-menopausal female relative)

Did you know?

You may be able to participate in a 36 month research study of an investigational medication for osteoporosis if you...

• Are past menopause
• Have low bone density or osteoporosis
• Are over the age of 65

Qualified participants will receive study-related clinic evaluations, bone mineral density scans, a spine x-ray (to assess bone health), as well as the investigational study medication and Vitamin D and Calcium supplementation at no charge.
